When a chemical reaction occurs, it is accompanied by an energy change which may take any of several different forms. For example, the energy change involved in the combustion of fuels like kerosene, coal, wood, natural gas, etc., takes the form of heat and light. Electrical energy is obtained from chemical reactions in batteries. The formation of glucose, \( \text{C}_6\text{H}_{12}\text{O}_6 \), by the process of photosynthesis requires the absorption of light energy from the sun. Thus, we see that the energy change that accompanies a chemical reaction can take different forms. In this lesson, you shall study the reactions in which heat is either evolved or absorbed.

**Objectives**

After reading this lesson, you will be able to:

- define the commonly used terms in thermodynamics;
- differentiate between exothermic and endothermic reactions;
- explain the first law of thermodynamics;
- explain internal energy;
- define enthalpy and enthalpy change;
- state the relationship between enthalpy change and internal energy change;
- define enthalpy of formation, enthalpy of neutralisation and enthalpy of combustion;
- state the relationship between enthalpy of reaction and enthalpies of formation of reactants and products;
- solve numerical problems based on the enthalpy changes;
- state Hess’s law;
- calculate enthalpy of a reaction using Hess’s law;
11.1 Some Commonly Used Terms

In this lesson you would come across some frequently used terms. Let us understand the meaning of these terms first.

11.1.1 System and Surrounding

If we are studying the reaction of two substances A and B kept in a beaker, the reaction mixture of A and B is a system and the beaker and the room where it is kept are surroundings as shown in figure 11.1.

System is the part of the physical universe which is under study, while the rest of the universe is surroundings.

You know that hot tea/milk (let us call it a system) kept in a stoppered thermos flask remains hot for a couple of hours. If this flask is made of perfect insulating material, then there would be no exchange of matter or energy between the system and the surroundings. We call such a system an **isolated system**.

Isolated system is a system which can exchange neither matter nor energy with the surroundings.

If we keep hot tea/milk in a stoppered stainless steel flask, it will not remain hot after some time. Here energy is lost to the surroundings through the steel walls, but due to stopper, the matter will not be lost. We call this system a **closed system**.

Closed system is a system which can exchange energy but not matter with the surroundings.

If we keep stainless steel flask or thermos flask open, some matter will also be lost due to evaporation along with energy. We call such a system an open system. Plants, animals, human beings are all examples of open systems, because they continuously exchange matter (food, etc) and energy with the surroundings.

Open system is a system which can exchange both energy and matter with surroundings.
11.1.2. State of a System

We describe the state of a system by its measurable properties. For example, we can describe the state of a gas by specifying its pressure, volume, temperature etc. These variable properties are called state variables or state functions. Their values depend only on the initial and final state of the system and not on the path taken by the system during the change. When the state of a system changes, the change depends only on the initial and the final state of the system (Fig 11.2).

![Diagram of state change](image)

**Fig. 11.2**: Change of state from initial state to final state through three paths I, II and III. The difference $p_2 - p_1$ and $T_2 - T_1$ are independent of the path since pressure and temperature are state functions.

State functions are those functions which depend only on the state of the system.

Change in state of a system is defined by giving the initial and the final state of the system. We can understand it by considering another example. We travel from one point to another. The distance travelled depends on the path or the route we take. But the separation between these two points on the earth is fixed. Thus, separation is a state function, but not the distance travelled.

11.1.3 Properties of a System

As stated earlier, the measurable properties of a system are called state variables. They may be further divided into two main types.

(i) **Extensive property** (variable) is one whose value depends upon the size of the system. For example, volume, weight, heat, etc.

(ii) **Intensive property** (variable) is one whose value is independent of the size of the system. For example, temperature, pressure, refractive index, viscosity, density, surface tension, etc.
You may note that an extensive property can become an intensive property by specifying a unit amount of the substance concerned. For example, mass and volume are extensive properties, but density (mass per unit volume) and specific volume (volume per unit mass) are intensive properties.

### 11.1.4 Types of Processes

Let us first understand what we mean by a process. Suppose we want to raise the temperature of the system. We may do it by heating it. Here, heating is the process.

**The method of bringing about a change in state is called process.**

Processes could be of different types. The different types of processes are explained below.

i) **Isothermal process**: Ice melts at 273 K and 1 atm pressure. The temperature does not change as long as the process of melting goes on. Such processes are examples of isothermal process. We can define *isothermal process* as follows.

*When the temperature of the system remains constant during various operations, then the process is said to be isothermal. This is attained either by removing heat from the system or by supplying heat to the system.*

ii) **Adiabatic Process**: If an acid is mixed with a base in a closed thermos flask, the heat evolved is retained by the system. Such processes are known as adiabatic processes because the thermos flask does not allow exchange of heat between the system and the surroundings. Adiabatic process can be defined as follows:

*In an adiabatic process there is no exchange of heat between the system and the surroundings. Thus, in adiabatic processes there is always a change in temperature.*

iii) **Reversible Process**: In a reversible process, the initial and the final states are connected through a succession of equilibrium states. All changes occurring in any part of the process are exactly reversed when it is carried out in the opposite direction. Thus both the systems and its surroundings must be restored exactly to their original state, when the process has been performed and then reversed.

Let us understand it by an example. Imagine a liquid in equilibrium with its vapour in a cylinder closed by a frictionless piston, and placed in a constant temperature bath as shown in figure 11.3. If the external pressure on the piston is increased by an infinitesimally small amount, the vapours will condense, but the condensation will occur so slowly that the heat evolved will be taken up by the temperature bath. The temperature of the system will not rise, and the pressure above this liquid will remain constant. Although condensation of the vapor is taking place, the system at every instant is in the state of equilibrium. If the external pressure is made just smaller than the vapour pressure, the liquid will vaporize extremely slowly, and again temperature and pressure will remain constant.
Reversible processes are those processes in which the changes are carried out so slowly that the system and surroundings are always in equilibrium.

iv) Irreversible Processes: In the above example rapid evaporation or condensation by the sudden decrease or increase of the external pressure, will lead to non-uniformity in temperature and pressure within the system and the equilibrium will be disturbed. Such processes are called as irreversible processes.

11.1.5 Standard States

You have seen that a system is described by the state variables. In order to compare the energies for different compounds, a standard set of conditions is chosen. This refers to the condition of 1 bar pressure at any specified temperature, with a substance in its most stable form.

11.2 Exothermic and Endothermic Reactions

(i) Add a few cm$^3$ of dilute hydrochloric acid in a test tube containing a few pieces of granulated zinc and observe the evolution of a gas. Feel the test tube. It would be hot.

(ii) You must have observed that when some water is added to quick lime to prepare white wash, a lot of heat is evolved.

(iii) When a fuel like cooking gas or coal is burnt in air, heat is evolved besides light. Many chemical reactions lead to release of energy (heat) to the surroundings. We call these type of reactions as exothermic reactions.

Exothermic reactions are those reactions which proceed with the evolution of heat.
Let us now consider the following reactions:

(i) Add a small amount of solid ammonium chloride in a test tube half-filled with water. Shake and feel the test tube. It will feel cold.

(ii) Similarly repeat this experiment with potassium nitrate and feel the test tube, it will feel cold.

(iii) Mix barium hydroxide with ammonium chloride in small quantities in water taken in a test tube. Feel the test tube. It will be cold.

In all the above processes we see that heat is absorbed by the system from the surroundings. Such reactions are called **endothermic reactions**.

**Endothermic reactions are those reactions which proceed with the absorption of heat from the surroundings.**

### 11.3 Thermochemical Equations

You are familiar with equations for chemical reactions. Now we shall write the chemical equations which will specify heat energy changes and states of the reactants and products. These are called the thermochemical equations. For writing these equations, we follow the conventions listed below:

(i) The heat evolved or absorbed in a reaction is affected by the physical state of the reacting substances. Therefore, gaseous, liquid and solid states are represented by putting symbols (g), (l), and (s) along side the chemical formulae respectively.

   For example, to represent burning of methane in oxygen, we write
   
   \[
   \text{CH}_4 (g) + 2\text{O}_2 (g) \rightarrow \text{CO}_2 (g) + 2\text{H}_2\text{O (l)} + \text{heat}
   \]

   In writing thermochemical reactions, we denote the amount of heat evolved or absorbed by a symbol \( \Delta H \). The amount of heat evolved or absorbed is written after the equation followed by semicolon. \( \Delta H \) is negative for exothermic reactions and it is positive for endothermic reactions.

   For example:

   An exothermic reaction is written as
   
   \[
   \text{CH}_4 (g) + 2\text{O}_2 (g) \rightarrow \text{CO}_2 (g) + 2\text{H}_2\text{O (l)} ; \Delta H = -891 \text{ kJ}
   \]

   Whereas an endothermic reaction is written as
   
   \[
   \text{H}_2 (g) + \text{I}_2 (g) \rightarrow 2\text{HI (g)} ; \Delta H = 52.2 \text{ kJ}
   \]

(ii) In case of elements which exhibit allotropy, the name of allotropic modification is mentioned. For example,

   \[
   \text{C (graphite), C (diamond), etc.}
   \]

(iii) The substances in aqueous solutions are specified using the symbol (aq). For example NaCl (aq) stands for an aqueous solution of sodium chloride.
(iv) Thermochemical equations may be balanced even by using fractional coefficients, if so required. The coefficients of the substances of the chemical equation indicate the number of moles of each substance involved in the reaction and the $\Delta H$ values given correspond to these quantities of substances.

(v) In case the coefficients are multiplied or divided by a factor, $\Delta H$ value must also be multiplied or divided by the same factor. In such cases, the $\Delta H$ value will depend upon the coefficients. For example, in equation.

$$\text{H}_2 (g) + \frac{1}{2} \text{O}_2 (g) \rightarrow \text{H}_2\text{O} (g) ; \Delta H = -242 \text{ kJ}$$

If coefficients are multiplied by 2, we would write the equation

$$2\text{H}_2 (g) + \text{O}_2 (g) \rightarrow 2\text{H}_2\text{O} (g) ; \Delta H = 2 (-242) = -484 \text{ kJ}$$

### 11.4 The First Law of Thermodynamics

You have learnt that chemical reactions are accompanied by energy changes. How do we determine these energy changes? You know that we cannot create or destroy energy. Energy only changes from one form to another. This is the observation made by many scientists over the years. This observation has taken the form of first law of thermodynamics. It has been found valid for various situations. We state this law as follows:

Energy can neither be created nor destroyed. The total energy of the universe or an isolated system is constant.

Mathematically the first law of thermodynamics is stated as:

$$\Delta U = q + w \quad (11.1)$$

where $\Delta U =$ change in internal energy, $q =$ heat absorbed by the system, and $w =$ work done on the system. These terms are explained as:

#### 11.4.1 Internal Energy ($U$)

Every system has a definite amount of energy. This amount is different for different substances. It includes translational, vibrational and rotational energies of molecules, energy of electrons and nuclei.

The internal energy may be defined as the sum of the energies of all the atoms, molecules or ions contained in the system.

It is a state variable. It is not possible to measure the absolute values of internal energy. However, we can calculate the change in internal energy. If the internal energy of the system in the initial state is $U_1$ and that in the final state is $U_2$, then change in internal energy $\Delta U$ is independent of the path taken from the initial to the final state.

We can write this change as:

$$\Delta U = U_2 - U_1$$

The internal energy of the system can be changed in two ways:
(i) either by allowing heat to flow into the system or out of the system; and
(ii) by work done on the system or by the system

11.4.2 Heat\((q)\) and Work\((w)\)

Heat and work are not state functions. This is because the values of both \(q\) and \(w\) depend
upon the way in which the change is carried out.

Since the law deals with the transfer of heat and work, we assign some signs to these
quantities. Any thing which increases the internal energy of a system is given a positive
sign.

Heat given to the system \((q)\) and work done on the system \((w)\) are given positive signs.
Let us illustrate this with an example.

If a certain change is accompanied by absorption of 50 kJ of heat and expenditure of 30
kJ of work,

\[
q = + 50 \text{ kJ} \\
w = - 30 \text{ kJ}
\]

Change in internal energy \(\Delta U = (+ 50 \text{ kJ}) + (- 30 \text{ kJ}) = + 20 \text{ kJ}\)

Thus the system has undergone a net increase in the internal energy of –20 kJ.

Change in the internal energy of the surroundings will be 20 kJ.

11.4.3 Work of Expansion

Let us assume that pressure \(p\) is constant and the volume of the system changes from \(V_1\)
to \(V_2\). The work done by a system is given as

\[
w = - p (V_2 - V_1) = - p \Delta V
\]

(Here we have taken minus sign, because the work is done by the system). Let us substitute
the expression given for \(w\) in equation 11.1.

We get

\[
\Delta U = q - p \Delta V
\]

If the process is carried ot at constant volume, i.e. \(\Delta V = 0\), then

\[
\Delta U = q_v
\]

The subscript \(v\) in \(q_v\) denotes that volume is constant.

The equation 11.4 shows that we can determine internal energy change if we measure
the heat gained or lost by the system at constant volume. However, in chemistry, the
chemical reactions are generally carried out at constant pressure (atmospheric pressure).
What do we do then? Let us define another state function, called, enthalpy.

11.4.4 Enthalpy\((H)\)

For measuring heat lost or gained at constant pressure, we define a new state function
called enthalpy. It is denoted by the symbol \(H\) and is given by
**Chemical Thermodynamics**

\[ H = U + p \, V \]  

(11.5)

Enthalpy change, \( \Delta H \), is given by

\[ \Delta H = \Delta U + \Delta (pV) \]  

(11.6)

or \( \Delta H = \Delta U + p \, \Delta V + V \, \Delta p \)

If the change is carried out at constant pressure, then \( \Delta p = 0 \). The equation 11.6 will become

\[ \Delta H = \Delta U + p \, \Delta V \text{ (at constant pressure)} \]  

(11.7)

Substituting the value of \( \Delta U \) from equation 11.3 in equation 11.7, we get

\[ \Delta H = q - p \, \Delta V + p \, \Delta V = q \text{ (at constant pressure)} \]

We denote \( q \) at constant pressure by \( q_p \), hence

\[ \Delta H = q_p \]  

(11.8)

Equation 11.8 shows that by measuring heat lost or gained at constant pressure, we can measure enthalpy change for any process.

### 11.4.5 Relation between \( \Delta H \) and \( \Delta U \)

For liquids and solids, the difference between \( \Delta r H \) and \( \Delta r U \) is not significant but for gasses, the difference is significant as we will see here.

Let \( V_A \) be the total volume of the gaseous reactants,

\( V_B \) the total volume of the gaseous products,

\( n_A \) the number of moles of gaseous reactants,

and \( n_B \) the number of moles of gaseous products, at constant pressure and temperature.

Then, using ideal gas law, we can write

\[ p \, V_A = n_A \, RT \]  

(11.9)

\[ p \, V_B = n_B \, RT \]  

(11.10)

Subtracting equation 11.9 from equation 11.10, we get

\[ p \, V_B - p V_A = n_B \, RT - n_A \, RT = (n_B - n_A) \, RT \]

\[ p \, (V_B - V_A) = p \, \Delta V = \Delta n_g \, RT \]

At constant pressure

\[ \Delta H = \Delta U + p \, \Delta V \]

Therefore \( \Delta H = \Delta U + \Delta n_g \, RT \)

Here \( \Delta n_g = \) (number of moles of gaseous products) - (number of moles of gaseous reactants)

Thus we can find the value of \( \Delta H \) from \( \Delta U \) or vice versa.
For solids and liquids $\Delta V$ is very small. We can neglect the term $p \Delta V$, hence $\Delta H$ is nearly the same as $\Delta U$.

### Intext Questions 11.1

1. Which of the following is false?
   (a) The reaction
   \[ \text{H}_2(g) + \text{Cl}_2(g) \rightarrow 2\text{HCl} (g) + 185 \text{ kJ} \]
   is endothermic.
   (b) Enthalpy change is a state function.
   (c) Standard state condition for a gaseous system is 1 bar pressure at a specified temperature.

2. For the reaction at 298 K,
   \[ \frac{1}{2} \text{N}_2(g) + \frac{3}{2} \text{H}_2 (g) \rightarrow \text{NH}_3(g); \Delta H = -46 \text{ kJ} \]
   (a) What is the value of $\Delta n_g$?
   ................................................................................................................................
   (b) Calculate the value of $\Delta U$ at 298 K?
   ................................................................................................................................

3. Which of the following will increase the internal energy of a system?
   (a) Heat given to the system
   (b) Work done by the system
   ................................................................................................................................

### 11.5 Standard Enthalpy of Reactions

Let us denote total enthalpy of reactants as $H_{\text{reactants}}$ and total enthalpy of products as $H_{\text{products}}$. The difference between these enthalpies, $\Delta H$, is the enthalpy of the reaction

\[ \Delta H = H_{\text{products}} - H_{\text{reactants}} \]

When $H_{\text{products}}$ is greater than $H_{\text{reactants}}$ then $\Delta H$ is positive and heat is absorbed in the reaction, and the reaction will be endothermic. For example,

\[ \text{H}_2(g) + \text{I}_2(g) \rightarrow 2\text{HI} (g); \Delta H = 52.5 \text{ kJ} \]

When $H_{\text{products}}$ is less than $H_{\text{reactants}}$ then $\Delta H$ is negative and heat is evolved in the reaction, and the reaction will be exothermic. For example,

\[ \text{CH}_4(g) + 2\text{O}_2(g) \rightarrow \text{CO}_2(g) + 2\text{H}_2\text{O}(l); \Delta H = -890.4 \text{ kJ} \]

Enthalpy of a reaction changes with pressure and temperature. It is convenient to report enthalpies of the reactions in terms of standard state of substances as we have defined earlier. When substances are in their standard states, we call the enthalpy of reaction as standard enthalpy of reaction. It is defined as the enthalpy change for a reaction, when the reactants and the products are in their standard states. It is denoted by \( \Delta H^0 \).

### 11.5.1 Enthalpy of formation \( (\Delta_f H^0) \)

The enthalpy change when one mole of a pure compound is formed from its elements in their most stable states is called the enthalpy of formation and is denoted by \( \Delta_f H^0 \).

When the reacting elements and the products formed are all in their standard states, the enthalpy change accompanying the chemical reaction is called the standard enthalpy of formation and is denoted by \( \Delta_f H^0 \). By convention, we take the standard enthalpy of formation of an element in its most stable state as zero.

For example:

\[ \text{C}_{(\text{Graphite})} + \text{O}_2(g) \rightarrow \text{CO}_2(g); \Delta_f H^0 = -393.5 \text{ kJ mol}^{-1} \]

This means that carbon dioxide is formed from its elements in their most stable states. Carbon in the form of graphite and at room temperature and gasesous O\(_2\) and CO\(_2\) being at 1 bar.

### 11.5.2 Enthalpy of Combustion \( (\Delta_{\text{comb}} H^0) \)

Enthalpy of combustion is the enthalpy change (heat evolved) accompanying the complete combustion of 1 mole of a substance in oxygen at a given temperature and 1 bar pressure.

For example:

\[ \text{C}_2\text{H}_5\text{OH}(l) + 3\text{O}_2(g) \rightarrow 2\text{CO}_2(g) + 3\text{H}_2\text{O}(l); \Delta_{\text{comb}} H^0 = -1365.6 \text{ kJ} \]

Enthalpy of combustion of \( \text{C}_2\text{H}_5\text{OH}(l) \) is \(-1365.6 \text{ kJ mol}^{-1} \).

### 11.5.3 Enthalpy of Neutralization \( (\Delta_{\text{neut}} H^0) \)

Enthalpy of neutralization is the enthalpy change (heat evolved) when one mole of hydrogen ions (H\(^+\)) is neutralized by one mole of hydroxyl ions (OH\(^-\)) in dilute aqueous medium to form water.

For example:

\[ \text{H}^+(aq) + \text{OH}^-(aq) \rightarrow \text{H}_2\text{O}(l); \Delta_{\text{neut}} H = -57 \text{ kJ/mol} \]

Enthalpy of neutralization of a strong acid with a strong base is always constant having a value of \(-57 \text{ kJ} \). However, enthalpy of neutralization of strong acid with a weak base or weak acid with a strong base will be different, because of varying degree of ionization of weak acids and bases.
There are two laws of thermochemistry: The Lavoisier–Laplace law and the Hess’s Law of Constant Heat Summation.

**Lavoisier – Laplace Law**: When a chemical equation is reversed, the sign of $\Delta H$ is changed. For example,

$$\text{N}_2 (g) + \text{O}_2 (g) \rightarrow 2\text{NO} (g); \Delta H = 180.5 \text{ kJ}$$

$$2\text{NO} (g) \rightarrow \text{N}_2 (g) + \text{O}_2 (g); \Delta H = -180.5 \text{ kJ}$$

**Hess’s Law of constant heat summation**: Hess’s law states that the enthalpy of reaction is independent of the number and the nature of the intermediate steps.

You have learnt that standard enthalpy change of the reaction

$$\text{C (graphite) + O}_2(g) \rightarrow \text{CO}_2(g)$$

is equal to $-393.5 \text{ kJ mol}^{-1}$. This value can be determined with the help of a calorimeter. However, there are some reactions for which the direct measurement of enthalpy in the laboratory is not possible. For example, the standard enthalpy change for the reaction,

$$\text{C (graphite) + } \frac{1}{2} \text{O}_2 (g) \rightarrow \text{CO} (g)$$

cannot be determined with the help of calorimeter because the combustion of carbon is incomplete unless an excess of oxygen is used. If excess of oxygen is used, some of the CO is oxidized to CO$_2$. How can then we determine the enthalpy change for such reactions when direct measurement is not possible?

Since $\Delta H$ is a state function, it is not dependent on the way the reactions are carried out. Let us carry out the reactions as follows.

1. First carry out the following reaction and let $\Delta H_1^0$ be the enthalpy change of the reaction.

$$\text{C (graphite) + O}_2(g) \rightarrow \text{CO}_2(g); \Delta H_1^0 = -393.5 \text{ kJ/mol.}$$

2. Now let us write the reaction for which we have to determine the enthalpy change of the reaction and let it be $\Delta H_2^0$

$$\text{C (graphite) + } \frac{1}{2} \text{O}_2 (g) \rightarrow \text{CO}(g); \Delta H_2^0 = ?$$

3. Let us carry out the following reactions and let $\Delta H_3^0$ be the enthalpy change of the reaction

$$\text{CO}(g) + \frac{1}{2} \text{O}_2(g) \rightarrow \text{CO}_2(g); \Delta H_3^0 = -283.0 \text{ kJ}$$

We have obtained the products CO$_2$(g) from carbon and oxygen through two routes, namely first as in step (1) and second as in step (2) + (3).
According to Hess’s Law

\[ \Delta_r H_1^0 = \Delta_r H_2^0 + \Delta_r H_3^0 \]

or

\[ \Delta_r H_2^0 = \Delta_r H_1^0 - \Delta_r H_3^0 \]

Fig 11.4 shows alternate paths for the conversion of carbon and oxygen to carbon dioxide.

**Fig 11.4 : Alternate paths for the conversion of carbon and oxygen to carbon dioxide**

The result of Hess’s law is that thermochemical equations can be added and subtracted just like algebraic equations to get the desired reaction. A useful practical application of this law is that we can calculate enthalpy changes for the reactions which cannot be studied directly as in the above case.

To obtain the enthalpy change for the reactions, we algebraically combine the known values of \( \Delta_r H^0 \) in the same way as the reactions themselves.

Thus

\[
\text{C(graphite) + O}_2 (g) \rightarrow \text{CO}_2 (g); \quad \Delta_r H_1^0 = -393.5 \text{ kJ/mol}
\]

\[- [\text{CO(graphite)} + \frac{1}{2} \text{O}_2(g) \rightarrow \text{CO}_2 (g)]; \quad \Delta_r H_3^0 = -283.0 \text{ kJ/mol} \]

\[
\text{C(graphite) +} \frac{1}{2} \text{O}_2 (g) \rightarrow \text{CO(g)}; \quad \Delta_r H_2^0 = \left[ (-393.5) - (-283.0) \right] = -110.5 \text{ kJ/mol}
\]

**Example 11.1** The heat evolved in the combustion of glucose is shown in the following equation:

\[
\text{C}_6\text{H}_{12}\text{O}_6 (s) + 6\text{O}_2(g) \rightarrow 6\text{CO}_2 (g) + 6\text{H}_2\text{O}(l); \quad \Delta_{\text{comb}}H = -2840 \text{ kJ/mol}
\]

How much energy will be required for the production of 1.08 g of glucose?

**Solution:** Glucose will be prepared by the reverse reaction.

\[
6\text{CO}_2(g) + 6\text{H}_2\text{O} (l) \rightarrow \text{C}_6\text{H}_{12}\text{O}_6 (s) + 6\text{CO}_2 (g); \quad \Delta H = 2840 \text{ kJ.}
\]

This equation refers to 1 mol of glucose (180 g of glucose).
Production of 180 g of glucose requires 2840 kJ of energy. Therefore, production of 1.08 g will require:

\[
\frac{2840 \text{ kJ}}{180 \text{ g}} \times 1.08 \text{ g} = 17.04 \text{ kJ}
\]

**Example 11.2** Calculate the standard enthalpy of formation of ethane, given that

\[
\text{C(graphite)} + \text{O}_2(g) \rightarrow \text{CO}_2(g); \Delta_f H^0 = -394 \text{ kJ mol}^{-1}
\]

\[
\text{H}_2(g) + \frac{1}{2} \text{O}_2(g) \rightarrow \text{H}_2\text{O}(l); \Delta_f H^0 = -286 \text{ kJ mol}^{-1}
\]

\[
\text{C}_2\text{H}_6(g) + \frac{7}{2} \text{O}_2(g) \rightarrow 2\text{CO}_2(g) + 3\text{H}_2\text{O}(l); \Delta_f H^0 = -1560 \text{ kJ mol}^{-1}
\]

**Solution:** Given that

\[
\text{C(graphite)} + \text{O}_2(g) \rightarrow \text{CO}_2(g); \Delta_f H^0 = -394 \text{ kJ/mol} \quad (1)
\]

\[
\text{H}_2(g) + \frac{1}{2} \text{O}_2(g) \rightarrow \text{H}_2\text{O}(l); \Delta_f H^0 = -286 \text{ kJ/mol} \quad (2)
\]

\[
\text{C}_2\text{H}_6(g) + \frac{7}{2} \text{O}_2(g) \rightarrow 2\text{CO}_2(g) + 3\text{H}_2\text{O}(l); \Delta_f H^0 = -1560 \text{ kJ/mol} \quad (3)
\]

The required equation is

\[
2\text{C(graphite)} + 3\text{H}_2(g) \rightarrow \text{C}_2\text{H}_6(g); \Delta_f H^0 = ? \quad (4)
\]

To obtain the above equation, multiply equations (1) by 2 and equation (2) by 3 and then add both the equations we get

\[
2\text{C(graphite)} + 3\text{H}_2(g) + \frac{7}{2} \text{O}_2(g) \rightarrow 2\text{CO}_2(g) + 3\text{H}_2\text{O}(l); \Delta_f H^0 = -1656 \text{ kJ/mol} \quad (5)
\]

(where \(\Delta_f H^0 = 2\Delta_f H^0_1 + 3\Delta_f H^0_2 = 2 \times (-394) + 3 \times (-286) = -1656 \text{ kJ/mol}\))

Subtract equation (3) from equation (5) to get the equation (4)

\[
2\text{C(graphite)} + 3\text{H}_2(g) \rightarrow \text{C}_2\text{H}_6(g);
\]

where \(\Delta_f H^0 = -1656 - (-1560) = -96 \text{ kJ/mol}\)

Thus, standard enthalpy of formation of ethane is -96 kJ/mol

### Intext Questions 11.2

1. Which of the following is true?
   (a) Enthalpy of formation is the heat evolved or absorbed when one gram of a substance is formed from its elements in their most stable states.
(b) When one mole of H\(^+\) (aq) and 1 mole of OH\(^-\) (aq) react, 57.1 kJ of energy is absorbed.

(c) In the thermochemical equation,

\[
\text{C(graphite)} + \text{O}_2 (g) \rightarrow \text{CO}_2 (g) ; \Delta_f H^0 = -394 \text{ kJ mol}^{-1}
\]

\(\Delta_f H^0\) is known as enthalpy of formation of CO\(_2\) (g)

2. Calculate the enthalpy change for complete combustion of 29.0 g of butane, if

\[
\text{C}_4\text{H}_{10}(g) + \frac{3}{2} \text{O}_2 (g) \rightarrow 4\text{CO}_2 (g) + 5\text{H}_2\text{O} (l) ; \Delta_{\text{comb}} H^0 = -2658 \text{ kJ}
\]

3. Calculate the standard enthalpy of the reaction

\[
2\text{H}_2\text{S}(g) + \text{SO}_2(g) \rightarrow 3\text{S} (s) + 2\text{H}_2\text{O} (l)
\]
given that

\[
\Delta_f H^0 (\text{H}_2\text{S}) = -20.6 \text{ kJ mol}^{-1}
\]
\[
\Delta_f H^0 (\text{SO}_2) = -296.9 \text{ kJ mol}^{-1}
\]
\[
\Delta_f H^0 (\text{H}_2\text{O}) = -289.9 \text{ kJ mol}^{-1}
\]

### 11.7 Bond Enthalpies

In a chemical reaction, you have seen that energy is either absorbed or evolved. Do you know the origin of this change in energy? You know that bonds are broken and new bonds are formed in chemical reactions. Energy changes take place in breaking some bonds of the reactants and in forming new bonds of the products. So the energy changes in a chemical reaction are a result of energy changes in breaking and forming of bonds. Let us consider the gaseous reactions, because in these, we encounter the energy changes due to breaking and forming of bonds only.

At high temperature, hydrogen molecules dissociate into atoms as

\[
\text{H}_2(g) \rightarrow \text{H} (g) + \text{H}(g) ; \Delta H = 435 \text{ kJ/mol}
\]

The heat absorbed in this reaction is used to break the chemical bonds holding the hydrogen atoms together in the \(\text{H}_2\) molecules. For a diatomic molecule like \(\text{H}_2(g)\), we define **bond dissociation energy** as the enthalpy change of the reaction in which one mole of the gaseous molecules are dissociated into gaseous atoms.

Now, let us consider a polyatomic molecule like \(\text{H}_2\text{O}(g)\). The dissociation may involve fragmenting the molecules into an atom and a group of atoms, called a radical, as in

\[
\text{H}_2\text{O} (g) \rightarrow \text{H} (g) + \text{OH} (g) ; \Delta_f H^0 = 502 \text{ kJ/mol}
\]

\[
\text{OH}(g) \rightarrow \text{O}(g) + \text{H} (g) ; \Delta_f H^0 = 427 \text{ kJ/mol}
\]

In the first reaction, one of the two OH bonds in \(\text{H}_2\text{O} (g)\) dissociates with an enthalpy change of 502 kJ/mol and in the second reaction, second OH bond dissociates with an enthalpy change of 427 kJ/mol. It is clear that the dissociation energy of the O – H bond is sensitive to its environment. However, the difference is not very large. We take the
Chemical energetics

average value (464.5 kJ/mol in this case) in case of polyatomic molecules and call it bond enthalpy.

Bond enthalpy is defined as the average amount of enthalpy change involved in the dissociation of one mole of bonds present in different gaseous compounds.

Now you know the distinction between bond dissociation enthalpy and bond enthalpy. Bond dissociation enthalpy refers to breaking a particular bond in a particular molecule whereas bond enthalpy is the average value of bond dissociation energies for a given type of bond. The bond enthalpies of some bonds are listed in table 11.1.

By using bond enthalpies (B.E.) it is possible to estimate the energy released when a gaseous molecule is formed from its gaseous atoms. For example, the energy released at constant pressure for the reaction \( \Delta_r H \),

\[
3H(g) + C(g) + Cl(g) \rightarrow CH_3Cl(g)
\]
is the sum of the energies of three C – H bonds, and one C – Cl bond, all taken with a negative sign because energy is released. Using the values of bond enthalpies (B.E.) from table 11.1 we get,

\[
\Delta_r H = -3 \times \text{B.E. (C – H)} – \text{B.E. (C – Cl)}
\]

\[
= (-3 \times 415 – 335) \text{ kJ mol}^{-1}
\]

\[
= (-1245 – 335) \text{ kJ mol}^{-1}
\]

\[
= – 1574 \text{ kJ mol}^{-1}
\]

We will now show you how to use bond enthalpy data to estimate the enthalpy of a reaction, when direct calorimetric data are not available. Note that in section 11.7 we used enthalpy of formation data to estimate enthalpy of a reaction. In principle, bond enthalpy data can be used to calculate \( \Delta_r H \) for a chemical reaction occurring in gaseous state by making use of difference in energy absorbed in breaking the bonds in reactants and energy released in formation of bonds in products.

\[
\Delta_r H = \Sigma \text{B.E. (reactants)} – \Sigma \text{B.E. (products)}
\]

\[
\text{(11.10)}
\]

### Example 11.3: Use bond enthalpy data given in table 11.1 to calculate the enthalpy of the reaction.

\[
\text{CH}_3(g) + \text{Cl}_2(g) \rightarrow \text{CH}_3\text{Cl}(g) + \text{HCl}(g)
\]

**Solution:**

1. Write the equation using structural formula

\[
\begin{array}{c}
\text{H} \\
\text{H} - \text{C} - \text{H} \\
\text{H}
\end{array} +
\begin{array}{c}
\text{H} \\
\text{Cl} - \text{Cl}
\end{array} \rightarrow
\begin{array}{c}
\text{H} - \text{C} - \text{Cl} \\
\text{H}
\end{array} +
\begin{array}{c}
\text{H} - \text{Cl} \\
\text{H}
\end{array}
\]

2. List the bonds broken and bonds formed under the equation as shown

\[
\begin{array}{c}
\text{H} \\
\text{H} - \text{C} - \text{H} + \text{Cl} - \text{Cl} \rightarrow \text{H} - \text{C} - \text{Cl} + \text{H} - \text{Cl}
\end{array}
\]

- number of bonds broken: 
  - C – H = 4
  - Cl – Cl = 1

- number of bonds formed: 
  - C – Cl = 1
  - H – Cl = 1
  - C – H = 3

3. Look up the values of bond enthalpies for the bonds in the reactants and products and list them as shown

<table>
<thead>
<tr>
<th>Reactants</th>
<th>Products</th>
</tr>
</thead>
<tbody>
<tr>
<td>B.E. (C – H) = 435 kJ mol(^{-1})</td>
<td>B.E. (Cl – C) = 339 kJ mol(^{-1})</td>
</tr>
<tr>
<td>B.E. (Cl – Cl) = 242 kJ mol(^{-1})</td>
<td>B.E. (H – Cl) = 431 kJ mol(^{-1})</td>
</tr>
<tr>
<td>B.E. (C – H) = 435 kJ/mol</td>
<td>B.E. (C – H) = 435 kJ/mol</td>
</tr>
</tbody>
</table>

4. Use equation 11.10,
Enthalpy of the reaction $\Delta H = \Sigma \text{B.E. (reactants)} - \Sigma \text{B.E. (products)}$

$= 4[\text{B.E. (C – H)} + \text{B.E. (C – Cl)}] - [\text{B.E. (C – Cl)} + \text{B.E. (H – Cl)} + 3 \text{B.E. (C – H)}]$

$= [4 \times 435 + 242] - [339 + 431 + 3 \times 435] = -93 \text{ kJ}$

Now let us take one example in which we calculate the enthalpy of a reaction using

(i) Enthalpy of formation data

(ii) Bond enthalpy data.

**Example 11.4**: Calculate $\Delta H^\circ$ for the reaction

$$\text{Cl}_2 (g) + 2\text{HF} (g) \rightarrow 2\text{HCl} (g) + \text{F}_2 (g)$$

(a) Using enthalpy of formation data

$\Delta H^\circ (\text{HCl}) = -92.5 \text{ kJ}$

$\Delta H^\circ (\text{HF}) = -269 \text{ kJ}$

(b) Using bond enthalpy data

B.E. (H – Cl) = 431 kJ mol$^{-1}$

B.E. (F – F) = 155 kJ mol$^{-1}$

B.E. (H – F) = 563 kJ mol$^{-1}$

B.E. (Cl – Cl) = 242 kJ mol$^{-1}$

**Solution**: (a) Using enthalpy of formation of compounds,

$$\Delta H = [2\Delta H^\circ (\text{HCl}) + \Delta H^\circ (\text{F}_2)] - [2\Delta H^\circ (\text{HF}) + \Delta H^\circ (\text{Cl}_2)]$$

$= [2 \times (-92.5) + 0] - [2 \times (-269) + 0] \text{ kJ}$

$= -185 \text{ kJ} + 538 \text{ kJ}$

$= +353 \text{ kJ}$

(b) Using bond enthalpies

$\Delta H^\circ = \Sigma \text{B.E. (reactants bonds)} - \Sigma \text{B.E. (products bonds)}$

$= [\text{B.E. (Cl – Cl)} + 2\text{B.E. (H – F)}] - [2 \text{B.E. (H – Cl)} + \text{B.E. (F – F)}]$

$= [242 + 2 (563)] \text{ kJ} - [2 \times 431 + 155] \text{ kJ}$

$= 1368 \text{ kJ} - 1017 \text{ kJ}$

$\Delta H^\circ = 351 \text{ kJ}$

$\Delta H^\circ$ calculated by these two different methods are nearly the same.
Intext Questions 11.3

1. Write True or false

(a) Enthalpy of a reaction is equal to the sum of the enthalpy of formation of products minus the sum of the enthalpy of formation of the reactants.

(b) Enthalpy of formation of any elementary substance is equal to zero.

(c) If a reaction can be carried out in several steps, the enthalpy change for the overall reaction is equal to enthalpy change in the last step.

(d) Bond enthalpy and bond dissociation energy are same for polyatomic molecules.

2. Calculate the bond enthalpy of N – H in NH₃ (g), given

\[
\frac{1}{2} N₂(g) + \frac{3}{2} H₂(g) \rightarrow NH₃(g); \quad \Delta H° = -46 \text{ kJ mol}^{-1}
\]

\[
\frac{1}{2} H₂(g) \rightarrow H(g); \quad \Delta H° = 218 \text{ kJ mol}^{-1}
\]

\[
\frac{1}{2} N₂(g) \rightarrow N(g); \quad \Delta H° = 973 \text{ kJ mol}^{-1}
\]

3. Calculate the enthalpy of the reaction

\[
H₂(g) + Cl₂(g) \rightarrow 2HCl(g)
\]

given;

Bond enthalpy (H - H) = 435 kJ mol⁻¹

Bond enthalpy (Cl - Cl) = 242 kJ mol⁻¹

Bond enthalpy (H - Cl) = 431 kJ mol⁻¹

What You Have Learnt

- System is the part of the physical universe which is under study, while the rest of the universe is surroundings.
- Isolated system is a system which can exchange neither matter nor energy with the surroundings.
- Closed system is a system which can exchange energy but not the matter with the surroundings.
- Open system is a system which can exchange both energy and matter with the surroundings.
- State functions are those functions which depend only on the state of the system.
Chemical energetics

- Extensive properties depend upon the size of the system whereas intensive properties do not depend upon the size of the system.

- When the temperature of the system is kept constant during various operations then the process is said to be isothermal.

- In an adiabatic process there is no exchange of heat between the system and the surroundings.

- Reversible processes are those processes in which the changes are carried out so slowly that the system and surrounding are always in equilibrium.

- Exothermic reactions are those reactions which proceed with the evolution of heat.

- Endothermic reactions are those which proceed with absorption of heat from the surroundings.

- First law of Thermodynamics states that energy can neither be created nor destroyed.

- Internal energy is the sum of the energies of all the atoms, molecules or ions contained in the system.

- The state function enthalpy (H) is given by the relation \( H = U + PV \).

- When a chemical equation is reversed, the sign of \( \Delta H \) is also reversed.

- The enthalpy of reaction is independent of the number and nature of the intermediate steps.

- Bond enthalpy is the average amount of bond dissociation enthalpies for a given type of bond present in different gaseous compounds, when one mole of bonds is broken in the gaseous state.

Terminal Exercise

1. Enthalpy of combustion of ethyl alcohol, \( \text{C}_2\text{H}_5\text{OH} \), is \(-950 \text{ kJ mol}^{-1} \). How much heat is evolved when one gram of ethyl alcohol burns?

2. Given:

\[
\text{C}_2\text{H}_2(\text{g}) + \frac{5}{2} \text{O}_2(\text{g}) \rightarrow 2\text{CO}_2(\text{g}) + \text{H}_2\text{O}(\text{l}) ; \Delta_{\text{comb}}H = -1299 \text{ kJ/mol}
\]

\[
\text{C( graphite)} + \text{O}_2(\text{g}) \rightarrow \text{CO}_2(\text{g}) ; \Delta_fH = -393 \text{ kJ/mol}
\]

\[
\text{H}_2(\text{g}) + \frac{1}{2} \text{O}_2(\text{g}) \rightarrow \text{H}_2\text{O} (\text{l}) ; \Delta_fH = -285.5 \text{ kJ/mol}
\]

Calculate enthalpy of formation of \( \text{C}_2\text{H}_2(\text{g}) \)

3. Calculate the enthalpy of combustion of propane

\[
\text{C}_3\text{H}_8(\text{g}) + 5\text{O}_2(\text{g}) \rightarrow 3\text{CO}_2(\text{g}) + 4\text{H}_2\text{O} (\text{l})
\]
Given the following:

\[ \text{H}_2(g) + \frac{1}{2} \text{O}_2(g) \rightarrow \text{H}_2\text{O} (l); \Delta H = -285.5 \text{ kJ/mol} \]

\[ \text{C(s)} + \text{O}_2(g) \rightarrow \text{CO}_2(g); \Delta H = -393 \text{ kJ/mol} \]

\[ 3\text{C (s)} + 4\text{H}_2(g) \rightarrow \text{C}_3\text{H}_8(g); \Delta H = -104 \text{ kJ/mol} \]

4. When two moles of \text{H}_2 and one mole of \text{O}_2 react to produce two moles of gaseous water at 373 K and 1 bar pressure, a total of 484 kJ are evolved. What are (a) \( \Delta H \) and (b) \( \Delta U \) for the production of a single mole of \text{H}_2\text{O} (g).

5. Calculate enthalpy of the reaction:

\[ 2\text{Na}_2\text{O}_2 (s) + 2\text{H}_2\text{O} (l) \rightarrow 4\text{NaOH} (s) + \text{O}_2 (g) \]

Enthalpies of formation of \text{NaOH} (s), \text{Na}_2\text{O}_2 (s) and \text{H}_2\text{O} (l) are - 426.4 \text{ kJ mol}^{-1}, 504 \text{ kJ mol}^{-1} and - 285 \text{ kJ mol}^{-1} respectively.

6. Calculate the heat of formation of gaseous ethyl alcohol,

\[ 2\text{C(graphite)} + 3\text{H}_2(g) + \frac{1}{2} \text{O}_2(g) \rightarrow \text{C}_2\text{H}_5\text{OH} (g) \]

given that enthalpy of sublimation of graphite is 714 \text{ kJ/mol} and bond enthalpies of \text{H – H}, \text{O = O}, \text{C – C}, \text{C – H}, \text{C – O} and \text{O – H} are respectively 435 \text{ kJ/mol}^{-1}, 498 \text{ kJ/mol}^{-1}, 347 \text{ kJ/mol}^{-1}, 415 \text{ kJ/mol}^{-1}, 355 \text{ kJ/mol}^{-1} and 462 \text{ kJ/mol}^{-1} respectively.

### Answers to Intext Questions

#### 11.1

1. (a)

2. (a) \( \Delta n = 1 - \frac{1}{2} - \frac{3}{2} = -1 \)

   (b) \[ \Delta U = \Delta H - \Delta n RT \]
   
   \[ = 46000 \text{ (J mol}^{-1}\text{)} - (-1) (8.314 \text{ Jk}^{-1} \text{ mol}^{-1}\text{)} \times (298 \text{ K}) \]
   
   \[ = - 46000 \text{ (J mol}^{-1}\text{)} + 2247.6 \text{ (J mol}^{-1}\text{)} \]
   
   \[ = - 43.5 \text{ kJ mol}^{-1}\]

3. (a)

#### 11.2

1. (c)

2. \(-1329 \text{ kJ}\)

3. \[ \Delta_f \text{H}^o = 2 \Delta_f \text{H}^o (\text{H}_2\text{O}) - 2\Delta_f \text{H}^o (\text{H}_2\text{S}) - \Delta_f \text{H}^o (\text{SO}_2) \]

   \[ = - 241.7 \text{ kJ}\]
11.3

1. (a) T
   (b) T
   (c) F
   (d) F

2. \[ \Delta rH^0 = \sum \text{B.E. (reactant bonds)} - \sum \text{B.E. (products bonds)} \]
   \[ \text{or } -46 \text{ (kJ mol}^{-1}\text{)} = 3 \times 218 \text{ (kJ mol}^{-1}\text{)} + 973 \text{ (kJ mol}^{-1}\text{)} - \text{B.E. (NH}_3\text{(g Bonds)}} \]
   \[ \text{B.E. (NH}_3\text{(g Bonds)} = 1673 \text{ kJ mol}^{-1} \]
   \[ \text{B.E. (N – H) = 557.7 kJ mol}^{-1} \]

3. \[ \Delta_rH^0 = -185 \text{ kJ mol}^{-1} \]
